## 1 Math Preliminaries

## 1.1 Introduction to Optimization

**Definition 1.1.1 (Optimization Problem).** The main optimization problem can be stated as follows

$$\min_{x \in S} f(x),\tag{1}$$

where

- x is the *optimization variable*,
- S is the feasible set, and
- *f* is the *objective function*.

**Remark 1.1**  $\max_{x \in S} f(x) = -\min_{x \in S} -f(x)$ . Hence, we will only study minimization problems.

#### Theorem 1.1.2 Solving an Optimization Problem

- Theoretical Analysis: analytic solution
- Numerical solution/optimization

#### Definition 1.1.3 (Solution Methods depend on the type of x, S, and f).

• When x is continuous (e.g.,  $\mathbb{R}$ ,  $\mathbb{R}^n$ ,  $\mathbb{R}^{m \times n}$ , ...), then the optimization problem stated in Eq. (1) is a *continuous optimization problem*. *It will also be the focus of this class*.

Opposite to continuous optimization problems, we have *discrete optimization problem* if x is discrete.

If x has both types of components, then we call the problem *mixed*.

- $\bullet$  Depending on S, we can have
  - Unconstrained problems: where  $S = \mathbb{R}^n$ ,  $S = \mathbb{R}^{m \times n}$ , ... (m, n are fixed).
  - Constrained problems: where  $S \subsetneq \mathbb{R}^n$ ,  $S \subsetneq \mathbb{R}^{m \times n}$ , ....

Both types of problems will be studied.

- Depending on f, we have
  - $Smooth\ optimization\ problems:\ f$  has first and/or second order derivatives.

Only smooth optimization problems will be studied.

- Non-smooth optimization problems: f is not differentiable.

**Definition 1.1.4 (Linear Optimization/Program).** If f is linear and S consists of linear constrains, then the optimization problem is called a *linear problem/program*.

#### **Example 1.1.5 Classification of Optimization Problems**

1. Consider the following problem

$$\min_{x_1, x_2, x_3} x_1^2 - 4x_1x_2 + 3x_2x_3 + \sin x_3$$

#### Solution 1.

- Optimization variable:  $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ .  $\longrightarrow$  continuous.
- Feasible set:  $S = \mathbb{R}^3$ .  $\longrightarrow$  unconstrained.
- Objective function:  $f(x_1, x_2, x_3) = x_1^2 4x_1x_2 + 3x_2x_3 + \sin x_3$ .  $\longrightarrow$  smooth but non-linear.

2. Consider the following problem

$$\max_{\substack{4x_1+7x_2+3x_3\leq 1\\x_1,x_2,x_3\geq 0}} x_1+2x_2+3x_3$$

#### Solution 2.

- Optimization variable:  $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ .  $\longrightarrow$  continuous.
- Feasible set:  $S = \{(x_1, x_2, x_3) : x_1, x_2, x_3 \ge 0, 4x_1 + 7x_2 + 3x_3 \le 1\} \subsetneq \mathbb{R}^3.$  constrained.
- Objective function:  $f(x_1, x_2, x_3) = x_1 + 2x_2 + 3x_3$ .  $\longrightarrow$  smooth and linear.

**Remark 1.2** This problem can be considered as the budget constrained optimization problem in Economics.

3. Consider the following problem

$$\min_{x_1, x_2 \ge 0} 4x_1 - 3|x_2| + \sin(x_1^2 - 2x_2)$$

#### Solution 3.

• Optimization variable:  $x = (x_1, x_2) \in \mathbb{R}^2$ .  $\longrightarrow$  continuous.

- - Feasible set:  $S = \{(x_1, x_2) : x_1, x_2 \ge 0\} \subsetneq \mathbb{R}62. \longrightarrow \text{constrained.}$
  - Objective function:  $f(x_1, x_2) = 4x_1 3|x_2| + \sin(x_1^2 2x_2)$ .  $\longrightarrow$  non-smooth and non-linear.

**Remark 1.3** In this particular problem,  $x_2 \ge 0$ , and so  $f(x_1, x_2) = 4x_1 - 3x_2 + \sin(x_1^2 - 2x_2)$  on the feasible set. Hence, this problem can be equivalently written as

$$\min_{x_1, x_2 \ge 0} 4x_1 - 3x_2 + \sin\left(x_1^2 - 2x_2\right),\,$$

which is a smooth optimization problem.

## 1.2 Linear Algebra Review

#### Example 1.2.1 Why linear algebra for optimization?

Consider  $\min_{x \in \mathbb{R}} f(x)$ , where  $f(x) = c + bx + ax^2, \ a, b, c \in \mathbb{R}$ .

- a > 0:  $x^* = -\frac{b}{2a}$  is a global minimum and  $f(x^*) = c \frac{b^2}{4a}$ .
- a < 0: no minimum exists.
- a = 0: f(x) = c + bx.
  - $b \neq 0$ : no minimum exists.
  - b = 0: f(x) = c, and every x is a minimum point.

We can approximate any smoothing function using Taylor's approximation and make them simple into the case discussed above.

## Theorem 1.2.2 Taylor's Approximation

$$f(x) = \underbrace{f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2}(x - x_0)^2}_{q(x)} + \underbrace{\varepsilon(x - x_0)(x - x_0)^2}_{\text{error}},$$

where  $\lim_{x\to x_0} \varepsilon(x-x_0)$ .

**Remark 1.4** The hope is that the quadratic approximation will inform us on the behavior of f near  $x_0$  and be useful for instance in referring  $x_0$  on the subject of optimality.

**Definition 1.2.3 (Quadratic Approximation in Higher Dimensions).** When d>1, we consider  $\min_{x\in\mathbb{P}^d}f(x)$ . Then, the *quadratic approximation* of f is defined as

$$q(x) \coloneqq c + \langle b, x \rangle + \langle x, Ax \rangle,$$

where  $c \in \mathbb{R}$ ,  $b \in \mathbb{R}^d$ ,  $A \in \mathbb{R}^{d \times d}$ .

**Remark 1.5** Then, to know if a minimum exists, we need information on the matrix A and the vector b.

**Definition 1.2.4 (Vector,**  $\mathbb{R}^d$ ). We define a *vector* in  $\mathbb{R}^d$  as a column vector.

$$x = \begin{pmatrix} x_1 \\ \vdots \\ x_d \end{pmatrix} \in \mathbb{R}^d, \ x_i \in \mathbb{R}.$$

On  $\mathbb{R}^d$ , we also have the following operations defined

• Addition:

$$\begin{pmatrix} x_1 \\ \vdots \\ x_d \end{pmatrix} + \begin{pmatrix} y_1 \\ \vdots \\ y_d \end{pmatrix} = \begin{pmatrix} x_1 + y_1 \\ \vdots \\ x_d + y_d \end{pmatrix}, \ x_i, y_i \in \mathbb{R}$$

Scalar multiplication:

$$\alpha \begin{pmatrix} x_1 \\ \vdots \\ x_d \end{pmatrix} = \begin{pmatrix} \alpha x_1 \\ \vdots \\ \alpha x_d \end{pmatrix}, \alpha, x_i \in \mathbb{R}$$

**Definition 1.2.5 (Basis of**  $\mathbb{R}^d$ ). A collection of vectors  $v_1 \dots, v_d \in \mathbb{R}^d$  is a *basis* in  $\mathbb{R}^d$  if  $\forall x \in \mathbb{R}^d$ ,  $\exists ! \alpha_1, \dots, \alpha_d \in \mathbb{R}$  *s.t.*  $x = \alpha_1 v_1 + \dots + \alpha_d v_d$ .

#### **Example 1.2.6 The Standard Basis**

The standard basis is defines as

$$e_i = \begin{pmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{pmatrix},$$

where 1 is at the *i*-th position for  $1 \le i \le d$ . Note that  $\forall x \in \mathbb{R}^d, \ x = x_1e_1 + \cdots + x_de_d$ .

#### Notation 1.7.

$$0_d = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}.$$

**Definition 1.2.8 (Inner Product).**  $\langle \cdot, \cdot \rangle : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$  is an *inner product* if

- (symmetry)  $\langle x, y \rangle = \langle y, x \rangle \quad \forall x, y \in \mathbb{R}^d$
- (additivity)  $\langle x, y + z \rangle = \langle x, y \rangle + \langle x, z \rangle \quad \forall x, y, z \in \mathbb{R}^d$
- (homogeneity)  $\langle \lambda x, y \rangle = \lambda \langle x, y \rangle \quad \forall x, y \in \mathbb{R}^d, \ \lambda \in \mathbb{R}$
- (positive definiteness)  $\langle x, x \rangle \geq \forall x \in \mathbb{R}^d$  and  $\langle x, x \rangle = 0 \iff x = 0$

#### **Example 1.2.9 Examples of Inner Products**

1. **Definition 1.2.10 (Dot Product).** The *dot product* of  $x, y \in \mathbb{R}^d$  is defined as

$$\langle x, y \rangle = x_1 y_1 + \dots + x_d y_d = \sum_{i=1}^d x_i y_i \quad \forall x, y \in \mathbb{R}^d.$$

It is also referred as the *standard inner product*, and we often use the notation  $x \cdot y$  to denote it.

2. **Definition 1.2.11 (Weighted Dot Product).** The *weighted dot product* of  $x, y \in \mathbb{R}^d$  with some weight w is defined as

$$\langle x, y \rangle_w = \sum_{i=1}^d w_i x_i y_i,$$

where  $w_1, \ldots, w_d > 0$  are called *weights*.

**Remark 1.6** When d=2, then  $\langle x,y\rangle=|x||y|\cos\angle(x,y)$ . Dot product measure how correlated are two vectors (with respect to their directions).

## **Definition 1.2.12 (Vector Norm).** $\|\cdot\|: \mathbb{R}^d \to \mathbb{R}$ is a *norm* if

- (non-negativity)  $||x|| \ge 0 \quad \forall x \in \mathbb{R}^d \text{ and } ||x|| = 0 \iff x = 0$
- (positive homogeneity)  $\|\lambda x\| = |\lambda| \|x\| \quad \forall \lambda \in \mathbb{R}, \ x \in \mathbb{R}^d$
- (triangular inequality)  $||x + y|| \le ||x|| + ||y|| \quad \forall x, y \in \mathbb{R}^d$ .

**Remark 1.7** *Vector norm introduces the notion of length of vectors in*  $\mathbb{R}^d$ .

#### **Example 1.2.13 Examples of Vector Norms**

• If  $\langle \cdot, \cdot \rangle$  is an inner product on  $\mathbb{R}^d$ , then

$$||x|| = \sqrt{\langle x, x \rangle} \quad \forall x \in \mathbb{R}^d$$

is a norm. For instance,

$$||x||_2 = \sqrt{x \cdot x} = \left(\sum_{i=1}^d x_i^2\right)^{\frac{1}{2}}.$$

This norm is called the *standard (Euclidean)* or  $\ell_2$  norm in  $\mathbb{R}^d$ .

• **Definition 1.2.14** ( $\ell_p$  **Norms).** Suppose  $p \ge 1$ , then

$$\|x\|_p := \left(\sum_{i=1}^d x_i^p\right)^{\frac{1}{p}}.$$

• Definition 1.2.15 ( $\infty$ -Norms).

$$||x||_{\infty} \coloneqq \max_{1 \le i \le d} |x_i| \quad \forall x \in \mathbb{R}^d.$$

**Remark 1.8**  $\lim_{p \to \infty} ||x||_p = ||x||_{\infty}$ .

## Theorem 1.2.16 Cauchy-Schwarz Inequality

Assume that  $\langle \cdot, \cdot \rangle : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$  is an inner product, then

$$\left|\langle x, y \rangle\right|^2 \le \langle x, x \rangle \cdot \langle y, y \rangle \quad \forall x, y \in \mathbb{R}^d.$$

In particular, if  $||x|| = \sqrt{\langle x, x \rangle}$ , then

$$|\langle x, y \rangle| \le ||x|| \cdot ||y|| \quad \forall x, y \in \mathbb{R}^d.$$

For the standard inner product, we have

$$\left| \sum_{i=1}^{n} x_i y_i \right| \le \|x\|_2 \cdot \|y\|_2 \quad \forall x, y \in \mathbb{R}^d.$$

The equality holds when  $\boldsymbol{x}$  and  $\boldsymbol{y}$  are linearly dependent.

**Definition 1.2.17 (Matrix).** Let  $d, m \in \mathbb{N}$ . We say that  $A \in \mathbb{R}^{d \times m}$  is a  $d \times m$  matrix if

$$A = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{d1} & a_{d2} & \cdots & a_{dm} \end{pmatrix} = \left(a_{ij}\right)_{i=1,j=1}^{d,m}$$

**Definition 1.2.18 (Operations with Matrices).** 

- Let  $A, B \in \mathbb{R}^{d \times m}$ , then  $\left(A + B\right)_{i,j} = a_{ij} + b_{ij} \quad \forall i, j$ .
- Let  $A \in \mathbb{R}^{d \times m}$  and  $\alpha \in \mathbb{R}$ , then  $(\alpha A)_{ij} = \alpha a_{ij} \quad \forall i, j$ .
- Let  $A \in \mathbb{R}^{d \times m}$  and  $B \in \mathbb{R}^{m,n}$ , then  $AB \in \mathbb{R}^{d \times n}$ , and  $\left(AB\right)_{ij} = \sum_{k=1}^{m} a_{ik} b_{kj} \quad \forall i,j$ .

**Remark 1.9** *Matrix multiplication is not commutative. In fact, if*  $A \in \mathbb{R}^{d \times m}$  *and*  $B \in \mathbb{R}^{m \times n}$ , then BA is defined if and only if n = d. In that case,  $AB \in \mathbb{R}^{d \times d}$  and  $BA \in \mathbb{R}^{m \times m}$ , and so if  $m \neq d$ , AB and BA have different sizes. Finally, even if m = d = n,  $AB \neq BA$  in general.

**Definition 1.2.19 (Linear Transformation).** The mapping  $\mathcal{L}: \mathbb{R}^m \to \mathbb{R}^d$  is called *linear* if  $\mathcal{L}(\alpha x_1 + \beta x_2) = \alpha \mathcal{L}(x_1) + \beta \mathcal{L}(x_2)$ .

#### Theorem 1.2.20 Matrices and Linear Transformation

 $\forall A \in \mathbb{R}^{d \times m}$ ,  $\mathcal{L}_A(x) = Ax$  is a linear mapping from  $\mathbb{R}^m$  to  $\mathbb{R}^d$ . Moreover,  $\forall \mathcal{L} : \mathbb{R}^m \to \mathbb{R}^d$  linear,  $\exists ! A \in \mathbb{R}^{d \times m}$  s.t.  $\mathcal{L} = \mathcal{L}_A$ .

**Proof 1.** Here, we offer an intuition on why this is true. Suppose  $A \in \mathbb{R}^{d \times m}$  and  $x \in \mathbb{R}^m$  s.t.

$$A = \begin{pmatrix} a_{11} & \cdots & a_{1m} \\ \vdots & \ddots & \vdots \\ a_{d1} & \cdots & a_{dm} \end{pmatrix} \quad \text{and} \quad x \in \begin{pmatrix} x_1 \\ \vdots \\ x_m \end{pmatrix} \in \mathbb{R}^{m \times 1}.$$

Then,  $Ax \in \mathbb{R}^{d \times 1}$  is the following

$$Ax = \begin{pmatrix} a_{11} & \cdots & a_{1m} \\ \vdots & \ddots & \vdots \\ a_{d1} & \cdots & a_{dm} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_m \end{pmatrix} = \begin{pmatrix} a_{11}x_1 + \cdots + a_{1m}x_m \\ \vdots \\ a_{d1}x_1 + \cdots + a_{dm}x_m \end{pmatrix} \in \mathbb{R}^{d \times 1}.$$

So, if  $\mathcal{L}_A(x) = Ax$  for  $x \in \mathbb{R}^m$ , then  $\mathcal{L}_A : \mathbb{R}^m \to \mathbb{R}^d$  is linear.

# Theorem 1.2.21 Matrix Multiplication as Composite Linear Transformations

Suppose  $\mathcal{L}_A: \mathbb{R}^m \to \mathbb{R}^d$  and  $\mathcal{L}_B: \mathbb{R}^n \to \mathbb{R}^m$ , where  $A \in \mathbb{R}^{d \times m}$  and  $B \in \mathbb{R}^{m \times n}$ . Define  $\mathcal{L}(x) = \mathcal{L}_A \circ \mathcal{L}_B(x) = \mathcal{L}_A(\mathcal{L}_B(x)) \quad \forall x \in \mathbb{R}^n$ . Then,  $\mathcal{L}: \mathbb{R}^n \to \mathbb{R}^d$ . Since  $\mathcal{L}_A$  and  $\mathcal{L}_B$  are linear, we found that  $\mathcal{L}$  is also linear. Hence,  $\mathcal{L} = \mathcal{L}_C$  f.s.  $C \in \mathbb{R}^{d \times n}$ . It turns out that C = AB.

**Definition 1.2.22 (Transpose of Matrix).** Let  $A \in \mathbb{R}^{d \times m}$ , then its transpose  $A^T \in \mathbb{R}^{m \times d}$ , and

$$\left(A^T\right)_{ij} = a_{ji}.$$

Corollary 1.2.23: If  $x, y \in \mathbb{R}^d$ , then  $\langle x, y \rangle = \sum_{i=1}^d x_i y_i = x^T y = x y^T$ .

**Proof 2.** Suppose 
$$x = \begin{pmatrix} x_1 \\ \vdots \\ x_d \end{pmatrix}$$
, then  $x^T = \begin{pmatrix} x_1 & \cdots & x_d \end{pmatrix}$ .

$$x^T y = \begin{pmatrix} x_1 & \cdots & x_d \end{pmatrix} \begin{pmatrix} y_1 \\ \vdots \\ y_d \end{pmatrix} = x_1 y_1 + \cdots + x_d y_d.$$

**Corollary 1.2.24 Cauchy-Schwarz:**  $|x^Ty| \le ||x||_2 ||y||_2$ .

**Definition 1.2.25 (Trace of a Matrix).** Assume that  $A \in \mathbb{R}^{d \times d}$ , the *trace* of A, denoted as Tr(A), is defined as

$$\operatorname{Tr}(A) = \sum_{i=1}^{d} a_{ii}.$$

**Definition 1.2.26 (Determinant of a Matrix).** Assume that  $A \in \mathbb{R}^{d \times d}$ , the *determinant* of A, denoted as det(A), is defined as

$$\det(A) = \sum_{\sigma \in S_d} (-1)^{i(\sigma)} a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{d\sigma(d)},$$

where  $S_d$  is the set of all possible permutation of size d and  $i(\sigma)$  denotes the sign of the permutation.

**Definition 1.2.27 (Eigenvalue and Eigenvector).** Assume that  $A \in \mathbb{R}^{d \times d}$ . We say that  $\lambda$  is an *eigenvalue* for A if  $\exists x \in \mathbb{R}^d \setminus \{0\}$  *s.t.*  $Ax = \lambda x$ . In this case, x is called an *eigenvector*.

**Definition 1.2.28 (Diagonalizability).** A matrix  $A \in \mathbb{R}^{d \times d}$  is called *diagonalizable* if  $\exists$  basis  $v_1, \ldots, v_d$  s.t.  $Av_i = \lambda v_i \quad \forall 1 \leq i \leq d$ .

# Theorem 1.2.29 Diagonalization, Singular Value Decomposition (SVD) of Squared Matrices

Assume that A is diagonalizable and

$$V = \begin{pmatrix} v_1 & v_2 & \cdots & v_d \end{pmatrix}.$$

Then,  $A = VDV^{-1}$ , where D is a diagonal matrix such that

$$D = \begin{pmatrix} \lambda_1 & 0 \\ & \ddots & \\ 0 & \lambda_d \end{pmatrix}.$$

#### **Example 1.2.30 Application of Diagonalization**

$$A^{2} = (VDV^{-1})(VDV^{-1}) = VD\underbrace{V^{-1}V}_{I}DV^{-1} = VD^{2}V^{-1}.$$

Generally,

$$A^{n} = VD^{n}V^{-1} = V \begin{pmatrix} \lambda_{1}^{n} & 0 \\ & \ddots & \\ 0 & v_{d}^{n} \end{pmatrix} V^{-1}.$$

## Remark 1.10 Remarks on Diagonalization

- There might be repeating eigenvalues. Typically, we enumerate  $\lambda$ 's s.t.  $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_d$ .
- *In general, it is hard to decide whether A is diagonalizable.* For example, rotation matrices have no eigenvectors nor eigenvalues.
- If A is symmetric; that is  $A = A^T$ , then A is diagonalizable. Moreover, we can choose basis  $v_1, \ldots, v_d$  s.t.

$$v_i^T v_j = \begin{cases} 0, & i \neq j \\ 1, & i = j \end{cases}.$$

Such bases are called orthonormal. In matrix form, if  $V = \begin{pmatrix} v_1 & v_2 & \cdots & v_d \end{pmatrix}$ , then

$$V^T V = \begin{pmatrix} v_1^T \\ \vdots \\ v_d^T \end{pmatrix} \begin{pmatrix} v_1 & \cdots & v_d \end{pmatrix} = I.$$

That is,  $V^T = V^{-1}$ , and hence  $A = VDV^{-1} = VDV^T$ .

## 1.3 Basic Topology

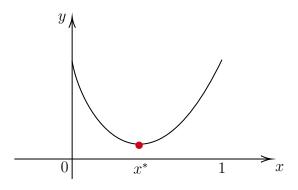

#### **Example 1.3.1 Introduction**

Consider the optimization problem  $\min_{x \in [0,1]} f(x)$ . Suppose that  $x^* \in [0,1]$  is a solution for this problem, then we have

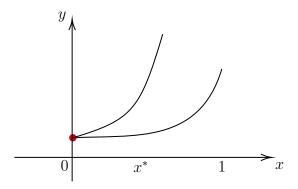

$$f(x) \ge f(x^*) \quad \forall x \in [0, 1].$$

Then, we can conduct a case study on the necessary condition we need to have on f'(x).

1. 
$$x^* \in (0,1) \implies f'(x^*) = 0$$
.

2. 
$$x^* = 0 \implies f'(x^*) \ge 0$$

3. 
$$x^* = 1 \implies f'(x^*) \le 0$$
.

**Definition 1.3.2 (Open/Closed Ball).** The *open ball* with center  $c \in \mathbb{R}^n$  and radius r > 0 is the set

$$B(c,r) := \{ x \in \mathbb{R}^n : ||x - c|| < r \}.$$

The *closed ball* with center  $c \in \mathbb{R}^n$  and radius r > 0 is the set

$$B[c,r] \coloneqq \{x \in \mathbb{R}^n : \|x - c\| \le r\}.$$

**Remark 1.11** The boundary is not included in an open ball.

**Definition 1.3.3 (Interior Point).** Assume that  $U \in \mathbb{R}^n$ . We say that  $x \in U$  is an *interior point* if  $\exists r > 0$  *s.t.*  $B(x, r) \subseteq U$ . The set of all interior points of U is denoted by int(U)

#### **Example 1.3.4 Interior Point Example**

Suppose U = [0, 1]. Prove that int(U) = (0, 1).

**Proof 1.** To prove this, we have to show  $int(U) \subseteq (0,1)$  and  $(0,1) \subseteq int(U)$ .

( $\supseteq$ ): Let  $x \in (0,1)$ . WTS:  $x \in int(U)$ . Take  $r = \min\{x, 1-x\}$ , then the open ball  $B(x,r) \subseteq$ 

*U. proof omitted.* So,  $x \in int(U)$ , and thus  $(0,1) \subseteq int(U)$ .  $\square$ 

 $(\subseteq)$ : Let  $x \in int(U)$ . WTS:  $x \in (0,1)$ . omitted.

**Definition 1.3.5 (Open Set).** A set  $U \subseteq \mathbb{R}^n$  is called *open* if int(U) = U.

#### **Example 1.3.6 Open Set Counterexample**

U = [0, 1] in Example 1.3.4 is not an open set.

**Remark 1.12** When f is defined over an open set U, then we can define differentiability on f on U.

**Definition 1.3.7 (Closed Set).** A set  $F \subseteq \mathbb{R}^n$  is called a *closed set* if  $\forall (x_n)_{n=1}^{\infty} \subseteq F$  such that  $\lim_{n \to \infty} x_n = x \implies x \in F$ .

#### **Example 1.3.8 Closed Set**

- Take  $F = \mathbb{R}^n$ , then F is a closed set because we have taken everything into the set.
- F = [0, 1] is closed.

**Proof 2.** Take  $x_1, x_2, \ldots, x_n \cdots \in [0, 1]$ . That is,  $0 \le x_n \le 1$ ,  $\forall n \ge 1$ . Then, set  $x = \lim_{n \to \infty} x_n$ . It must be that  $0 \le x \le 1$ , or  $x \in [0, 1]$ .

• F = (0, 1] is not closed.

**Proof 3.** Take  $x_1, \ldots, x_n, \cdots \in (0,1]$ , where  $x_n = \frac{1}{n} \quad \forall n \geq 1$ . Then,  $0 \leq x_n \leq 1$ .

However, notice that  $x = \lim_{n \to \infty} x_n = \lim_{n \to \infty} \frac{1}{n} = 0 \notin (0, 1]$ . Hence, F is not closed.

**Remark 1.13** In general, optimization problems are set on closed sets for otherwise, we cannot guarantee, in general, existence of optimal solutions.

#### Example 1.3.9 Optimization Problem on a Set that is not Cloased

Suppose f(x) = x and consider the optimization problem

$$\min_{0 < x \le 1} f(x) = \min_{0 < x \le 1} x.$$

Then we know that this problem does not have a solution.

#### Remark 1.14 A set can be neither open nor closed.

**Definition 1.3.10 (Boundary Points).** A point x is a *boundary point* for U if  $\forall r > 0$ , B(x,r) contains points from both U and its complement. The set of all boundary points of U is denoted by bd(U).

#### **Example 1.3.11 Boundary Pooints**

- $U = [0,1] \implies bd(U) = \{0,1\}.$
- $U = (0,1] \implies bd(U) = \{0,1\}.$

# 2 Unconstrained Optimization

# 3 Least Square

# 4 Constrained Optimization
